Facial animation is difficult to do convincingly, particularly when synchronizing with speech. There are various ways to automate facial animation:

- **Performance-driven animation**
- **Audio-driven animation**
- **Audio-visual text-to-speech synthesis (AVTTS)**

The problem with these solutions is they bring together software and data formats from different fields—in particular speech technology and graphics technology—that are not well integrated.

The Conversion of facial dynamics into animation is cumbersome, slow and offline.

• Lack of live connection between speech and rendering pipelines. Difficult to backtrack animation problems, or see outcome of edits in the speech processing level.

• No standard control interface for different facial models, so adaptation process must be repeated in each case.

The core of our solution is a platform independent C++ API.

Software framework called “Carnival” which places speech and graphics components within a single object-oriented system.

- Fast and automatic end-to-end processing
- Real-time animation and linked display of time-varying representations for instantaneous feedback/feed-forward information
- Standardized object interfaces for easy integration of new components

The API may be used for fast prototyping of automated animation systems

- Suitable for performance-driven, audio-driven, or AVTTS applications
- Our implemented tool built on the API is suitable for in-house industrial or academic use
